## Seaway Hotels Corporation

### CATASTROPHE RISK SUMMARY

February 24, 2023

Analysis Performed by:  
AmWINS Group, Inc.  
4725 Piedmont Row Drive, Suite 600  
Charlotte, NC 28210

## Executive Summary

AmWINS Group, Inc. performed a hurricane (named storm) analysis to calculate the potential loss for Seaway Hotels Corporation based on Risk Management Solutions (RMS) RiskLink Version 18.1 software. The analysis was performed to include the primary peril of Windstorm and the secondary perils of Storm Surge and Loss Amplification using the RMS Stochastic Event Rate Set. The data for this analysis was provided by Seaway Hotels Corporation and represents the most recent exposure for this account. AmWINS Group, Inc. reviewed and formatted the data for use in the RMS model based on the original data received.

### Exposure Summary

The Seaway Hotels Corporation account has 8 locations with a total insured value (TIV) of \$285,454,693. Building Values account for 83.6% of the TIV while Contents accounts for 10.3% of the TIV and Business Interruption accounts for 6.1% of the TIV.

For further exposure details see the Exposure Analysis section of the report which starts on page 11.

### Analysis Summary

The analysis was performed with a deductible structure of 5% per unit with \$2.5M max for Biltmore Hotel, Conference Center, and Golf Course, and \$1.5M max for Sheraton Sand Key Hotel and with no limits.

### Loss Summary

Based on RMS RiskLink Version 18.1 there is a 0.4% annual chance of one hurricane (named storm) event causing \$14,578,457 or more in loss net of the deductible structure and within the coverage layers being analyzed. This corresponds to a 250 year return period.

The Average Annual Loss (AAL), which corresponds to a pure premium number, for the Seaway Hotels Corporation account based on RMS RiskLink version 18.1 is \$233,432 net of the deductible structure and within the coverage layers being analyzed. This means that on a long-term average annual basis, the Seaway Hotels Corporation account is expected to sustain \$233,432 in hurricane (named storm) losses to the insurance carrier.

**\*\*Note:** loss amounts stated above are for the peril of Windstorm including Storm Surge and Loss Amplification using the RMS Stochastic Event Rate Set

For further loss details see the Detailed Loss Analysis section of the report on page 4.

For a breakdown of the locations that contribute the most to the AAL see the AAL by Location section of the report on page 5.

The Loss Estimates produced will help the Seaway Hotels Corporation account to:

- Identify areas of exposure concentration
- Identify locations that contribute the most to modeled loss estimates
- Understand hurricane (named storm) loss potential

**Detailed Loss Analysis**

**Exceedance Probability Analysis for Hurricane (Named Storm)**

The tables below illustrate the probability of losses exceeding various amounts due to one event in a given year as described by the Occurrence Exceedance Probability (OEP) curve. Losses are shown as Ground Up (no deductible or layering contemplated), Deductible (loss to deductible layer), and Net of Deductible and Layering (takes deductible into account and isolates layer being analyzed). The Average Annual Loss (AAL) is also shown along with the variability of this amount (Standard Deviation) which is representative of the uncertainty in the magnitude of losses from an occurring event.

For a discussion of RMS methodology for modeling PMLs and AALs see page 7.

## Discussion of RMS Methodology for Modeling PMLs and AALs

---

RMS determines catastrophic losses using complex software that simulates catastrophic events and determines losses from those events based on building characteristics. The process begins by entering building information into RMS (construction type, year built, occupancy, etc.) and the better information you have, the better (more accurate) the results will be. For missing characteristics, RMS uses default values based on attributes of the industry exposure.

Once information is loaded, RMS will run a series of catastrophic events (both historical and simulated) against those buildings. Each event run has a probability associated with it so as to tell how "likely" that type of event is to occur in a given year. Losses are determined on a per building, per event basis based on how the attributes of each event (wind speed, quake magnitude, etc.) would affect that type of building (based on the building characteristics entered). Engineering information has been gathered based on actual claim data and inspections to see how different types of buildings (age, construction, etc.) will react to either wind, storm surge, or an earthquake.

Losses from each building-event combination are used to come up with a distribution of losses based on probability of occurrence. Statistical methods determine this distribution which is called the EP (Exceedance Probability) Curve and it is used to derive Probable Maximum Loss (PML) numbers. This curve shows probability of exceedance on the y-axis and amount of loss on the x-axis so points on the curve are defined as the loss amount (from x-axis) that will be exceeded a certain percentage of the time (from y-axis) in a given year. Certain points from this curve are focused on, like a 1% probability of exceedance in a given year (the 1-in-100 year event, or 100-year PML) which means that losses will be greater than or equal to that loss amount 1% of the time in a given year. Different points can be chosen, but it must be understood that no one event in RMS is what you would call the 1-in-100 year (or 1-in-X year) event. All events are combined to generate a curve that tells what losses would be from a 1-in 100 year (or 1-in-X year) event.

Average Annual Loss (AAL) is also generated and this tells the amount of loss to be expected on an annual basis. This acts as a pure premium number even though catastrophes are not something that occur "on average" in insurance. AALs are calculated on a per building basis as the losses from each event are multiplied by the probability of such event occurring in a given year. These are then added up across all events. Once these are calculated for each building, all building AALs are added up to get the overall account AAL. No curve generation is done here so these numbers don't depend on the statistical methods employed in the generation of the EP Curve.

In short, RMS uses simulated and historical catastrophic events (hurricanes, earthquakes, etc.) to determine the exposure and vulnerability of a book of business to catastrophic losses. Engineering and claims data are used to determine vulnerability of buildings, and seismology and meteorology are used to determine the probability of earthquakes, hurricanes, or other events along with quake magnitudes, storm size, and event location. Simulated losses for buildings are generated and combined to give the overall loss picture for the account.

**Hurricane Intensity Definitions (Saffir-Simpson Scale)**

<b>CATEGORY:</b>	<b>WIND SPEED:</b>	<b>STORM EFFECTS:</b>
1	74-95 mph	Storm surge generally 4-5 ft above normal. No real damage to building structures. Damage primarily to unanchored mobile homes, shrubbery and trees. Also, some coastal road flooding and minor pier damage.
2	96-110 mph	Storm surge generally 6-8 feet above normal. Some roofing material, door and window damage to buildings. Considerable damage to vegetation, mobile homes and piers. Coastal and low-lying escape routes flood 2-4 hours before arrival of hurricane center. Small craft in unprotected anchorages break moorings.
3	111-130 mph	Storm surge generally 9-12 ft above normal. Some structural damage to small residences and utility buildings with a minor amount of curtainwall failures. Damage to shrubbery and trees with foliage blown off trees and large trees blown down. Mobile homes and poorly constructed signs are destroyed. Low-lying escape routes are cut by rising water 3-5 hours before arrival of the center of the hurricane. Flooding near the coast destroys smaller structures with larger structures damaged by battering from floating debris. Terrain continuously lower than 5 ft above mean sea level may be flooded inland 8 miles (13 km) or more. Evacuation of low-lying residences with several blocks of the shoreline may be required.
4	131-155 mph	Storm surge generally 13-18 ft above normal. More extensive curtainwall failures with some complete roof structure failures on small residences. Shrubs, trees, and all signs are blown down. Complete destruction of mobile homes. Extensive damage to doors and windows. Low-lying escape routes may be cut by rising water 3-5 hours before arrival of the center of the hurricane. Major damage to lower floors of structures near the shore. Terrain lower than 10 ft above sea level may be flooded requiring massive evacuation of residential areas as far inland as 6 miles (10 km).
5	>155 mph	Storm surge generally greater than 18 ft above normal. Complete roof failure on many residences and industrial buildings. Some complete building failures with small utility buildings blown over or away. All shrubs, trees, and signs blown down. Complete destruction of mobile homes. Severe and extensive window and door damage. Low-lying escape routes are cut by rising water 3-5 hours before arrival of the center of the hurricane. Major damage to lower floors of all structures located less than 15 ft above sea level and within 500 yards of the shoreline. Massive evacuation of residential areas on low ground within 5-10 miles (8-16 km) of the shoreline may be required.

**Catastrophe Modeling Terms**

<b>TERM:</b>	<b>DEFINITION:</b>
Aggregate Exceedance Probability (AEP)	The probability that the total cost of one or more occurrences will combine in a year to exceed a certain threshold.
Average Annual Loss (AAL)	The expected annual loss on a long-term basis. Mathematically, it is the expected value of the aggregate loss distribution.
Coefficient Variation (CV)	The spread of loss around the mean, reflecting the secondary uncertainty in the size of loss.
Loss Amplification	"Post loss inflation" of building materials/labor, typically applied only to building damage, and not to contents or business interruption components.
Exceedance Probability (EP)	The probability of exceeding specified loss thresholds. In risk analysis, this probability relationship is commonly represented as a curve which defines the probability of various levels.
Exposure Value	The total reported values at risk, potentially subject to a peril or event against which it is insured.
Geocoding	The process of associating an address with an estimate of latitude and longitude coordinates.
Gross Loss	The insurer's loss after deductibles, attachment point(s), and limits are applied, but before reinsurance.
Ground Up Loss	The total amount of loss sustained before deductibles, underlying coverages and reinsurance are applied.
Mean Damage Ratio	The ratio of the expected loss to the replacement value of exposed properties.
Occurrence Exceedance Probability (OEP)	The probability that a single occurrence will exceed a certain threshold.
Return Period	The expected length of time between recurrences of two events with similar characteristics. The return period can also refer to specific level of loss.
Secondary Peril (Subperil)	Hazards that are an additional source of loss to the primary peril. Examples include "storm surge" as a result of a hurricane, or "fire" as a direct result of an earthquake.
Storm Surge	The effect of flood caused by storm.
